5.2 Java reference

```
/* Java reference :
   References on Java IO, structures, etc.
*/
import java.io.*;
import java.lang.*;
import java.math.*;
import java.util.*;
/* Regular usage:
   Slower IO :
   Scanner in = new Scanner (System.in));
   Scanner in = new Scanner (new BufferedInputStream (System.in));
   Input :
   in.nextInt () / in.nextBigInteger () / in.nextBigDecimal () / in.nextDouble ()
   in.nextLine () / in.hasNext ()
   Output :
   System.out.print (...);
   System.out.println (...);
   System.out.printf (...);
   Faster IO :
   Shown below.
   BigInteger :
   BigInteger.valueOf (int) : convert to BigInteger.
   abs / negate () / max / min / add / subtract / multiply /
   divide / remainder (BigInteger) : BigInteger algebraic.
   gcd (BigInteger) / modInverse (BigInteger mod) /
   modPow (BigInteger ex, BigInteger mod) / pow (int ex) : Number Theory.
   not () / and / or / xor (BigInteger) / shiftLeft / shiftRight (int) : Bit operation.
   compareTo (BigInteger) : comparison.
   intValue () / longValue () / toString (int radix) : converts to other types.
   isProbablePrime (int certainty) / nextProbablePrime () : checks primitive.
   BigDecimal :
   consists of a BigInteger value and a scale.
   The scale is the number of digits to the right of the decimal point.
   divide (BigDecimal) : exact divide.
   divide (BigDecimal, int scale, RoundingMode roundingMode) :
   divide with roundingMode, which may be:
   CEILING / DOWN / FLOOR / HALF_DOWN / HALF_EVEN / HALF_UP / UNNECESSARY / UP.
   BigDecimal setScale (int newScale, RoundingMode roundingMode) :
   returns a BigDecimal with newScale.
   doubleValue () / toPlainString () : converts to other types.
   Arrays :
   Arrays.sort (T [] a);
   Arrays.sort (T [] a, int fromIndex, int toIndex);
   Arrays.sort (T [] a, int fromIndex, int toIndex, Comparator <? super T> comparator);
```

```

LinkedList <E> :
    addFirst / addLast (E) / getFirst / getLast / removeFirst / removeLast () :
        deque implementation.
    clear () / add (int, E) / remove (int) : clear, add & remove.
    size () / contains / removeFirstOccurrence / removeLastOccurrence (E) :
        deque methods.
    ListIterator <E> listIterator (int index) : returns an iterator :
        E next / previous () : accesses and iterates.
        hasNext / hasPrevious () : checks availability.
        nextIndex / previousIndex () : returns the index of a subsequent call.
        add / set (E) / remove () : changes element.
PriorityQueue <E> (int initcap, Comparator <? super E> comparator) :
    add (E) / clear () / iterator () / peek () / poll () / size () :
        priority queue implementations.
TreeMap <K, V> (Comparator <? super K> comparator) :
    Map.Entry <K, V> ceilingEntry / floorEntry / higherEntry / lowerEntry (K):
        getKey / getValue () / setValue (V) : entries.
    clear () / put (K, V) / get (K) / remove (K) : basic operation.
    size () : size.
StringBuilder :
    Mutable string.
    StringBuilder (string) : generates a builder.
    append (int, string, ...) / insert (int offset, ...) : adds objects.
    charAt (int) / setCharAt (int, char) : accesses a char.
    delete (int, int) : removes a substring.
    reverse () : reverses itself.
    length () : returns the length.
    toString () : converts to string.
String :
    Immutable string.
    String.format (String, ...) : formats a string. i.e. sprintf.
    toLowerCase / toUpperCase () : changes the case of letters.
*/
/* Examples on Comparator :
public class Main {
    public static class Point {
        public int x;
        public int y;
        public Point () {
            x = 0;
            y = 0;
        }
        public Point (int xx, int yy) {
            x = xx;
            y = yy;
        }
    };
    public static class Cmp implements Comparator <Point> {
        public int compare (Point a, Point b) {

5.5.1 Prefix sum of multiplicative functions

Define the Dirichlet convolution $f * g(n)$ as:

$$f * g(n) = \sum_{d=1}^n [d|n] f(n) g\left(\frac{n}{d}\right)$$

Assume we are going to calculate some function $S(n) = \sum_{i=1}^n f(i)$, where $f(n)$ is a multiplicative function. Say we find some $g(n)$ that is simple to calculate, and $\sum_{i=1}^n f * g(i)$ can be figured out in $O(1)$ complexity. Then we have

$$\begin{aligned}
\sum_{i=1}^n f * g(i) &= \sum_{i=1}^n \sum_d [d|i] g\left(\frac{i}{d}\right) f(d) \\
&= \sum_{\frac{i}{d}=1}^n \sum_{d=1}^{\left\lfloor \frac{n}{i} \right\rfloor} g\left(\frac{i}{d}\right) f(d) \\
&= \sum_{i=1}^n \sum_{d=1}^{\left\lfloor \frac{n}{i} \right\rfloor} g(i) f(d) \\
&= g(1)S(n) + \sum_{i=2}^n g(i)S\left(\left\lfloor \frac{n}{i} \right\rfloor\right) \\
S(n) &= \frac{\sum_{i=1}^n f * g(i) - \sum_{i=2}^n g(i)S\left(\left\lfloor \frac{n}{i} \right\rfloor\right)}{g(1)}
\end{aligned}$$

It can be proven that $\left\lfloor \frac{n}{i} \right\rfloor$ has at most $O(\sqrt{n})$ possible values. Therefore, the calculation of $S(n)$ can be reduced to $O(\sqrt{n})$ calculations of $S\left(\left\lfloor \frac{n}{i} \right\rfloor\right)$. By applying the master theorem, it can be shown that the complexity of such method is $O(n^{\frac{2}{3}})$.

Moreover, since $f(n)$ is multiplicative, we can process the first $n^{\frac{2}{3}}$ elements via linear sieve, and for the rest of the elements, we apply the method shown above. The complexity can thus be enhanced to $O(n^{\frac{2}{3}})$.

For the prefix sum of Euler's function $S(n) = \sum_{i=1}^n \varphi(i)$, notice that $\sum_{d|n} \varphi(d) = n$. Hence $\varphi * I(n) = id(n)$. (Define $I(n) = 1, id(n) = n$.) Now let $g(n) = I(n)$, and we have $S(n) = \sum_{i=1}^n i - \sum_{i=2}^n S\left(\left\lfloor \frac{n}{i} \right\rfloor\right)$.

For the prefix sum of Mobius function $S(n) = \sum_{i=1}^n \mu(i)$, notice that $\mu * I(n) = [n = 1]$. Hence $S(n) = 1 - \sum_{i=2}^n S\left(\left\lfloor \frac{n}{i} \right\rfloor\right)$.
